RUTGERS

Turfgrass Proceedings

THE NEW JERSEY TURFGRASS ASSOCIATION

In Cooperation With

RUTGERS COOPERATIVE EXTENSION
NEW JERSEY AGRICULTURAL EXPERIMENT STATION
RUTGERS, THE STATE UNIVERSITY OF NEW JERSEY
NEW BRUNSWICK

Distributed in cooperation with U.S. Department of Agriculture in furtherance of the Acts of Congress of May 8 and June 30, 1914. Cooperative Extension work in agriculture, home economics, and 4-H. Zane R. Helsel, Director of Extension. Rutgers Cooperative Extension provides information and educational services to all people without regard to sex, race, color, national origin, disability or handicap, or age. Rutgers Cooperative Extension is an Equal Opportunity Employer.

2001 RUTGERS TURFGRASS PROCEEDINGS

of the

New Jersey Turfgrass Expo December 11-13, 2001 Trump Taj Mahal Atlantic City, New Jersey

The Rutgers Turfgrass Proceedings is published yearly by the Rutgers Center for Turfgrass Science, Rutgers Cooperative Extension, and the New Jersey Agricultural Experiment Station, Cook College, Rutgers, The State University of New Jersey in cooperation with the New Jersey Turfgrass Association. The purpose of this document is to provide a forum for the dissemination of information and the exchange of ideas and knowledge. The proceedings provide turfgrass managers, research scientists, extension specialists, and industry personnel with opportunities to communicate with co-workers. Through this forum, these professionals also reach a more general audience, which includes the public.

This publication includes lecture notes of papers presented at the 2001 New Jersey Turfgrass Expo. Publication of these lectures provides a readily available source of information covering a wide range of topics and includes technical and popular presentations of importance to the turfgrass industry.

This proceedings also includes research papers that contain original research findings and reviews of selected subjects in turfgrass science. These papers are presented primarily to facilitate the timely dissemination of original turfgrass research for use by the turfgrass industry.

Special thanks are given to those who have submitted papers for this proceedings, to the New Jersey Turfgrass Association for financial assistance, and to those individuals who have provided support to the Rutgers Turfgrass Research Program at Cook College, Rutgers, The State University of New Jersey.

Dr. Ann Brooks Gould, Editor
Dr. Bruce B. Clarke, Coordinator

PERFORMANCE OF KENTUCKY BLUEGRASS CULTIVARS AND SELECTIONS IN NEW JERSEY TURF TRIALS

**Stacy A. Bonos, James A. Murphy, William A. Meyer, C. Reed Funk, William K. Dickson,
Eric Watkins, Ronald F. Bara, Dirk A. Smith, and Melissa M. Mohr¹**

Kentucky bluegrass (*Poa pratensis*) is the most widely used cool-season turfgrass in the United States. The popularity of Kentucky bluegrass is due to its ability to develop dense turfs of pleasing color and clean mowing quality in a wide range of soils and climates. Its extensive rhizome system provides excellent sod strength and the ability to recuperate after stress periods and fill in damaged areas quickly. Kentucky bluegrass is utilized on more than 35 million acres of pastures in the northeastern and northcentral United States, as well as large areas of Canada and Europe. Kentucky bluegrass is considered a premier lawn grass, contributing to the turf of over 40 million lawns throughout the subarctic, temperate, and subtropical (high altitude) climates of the United States.

There are three main uses of Kentucky bluegrass: forage, soil conservation, and specialized medium-high maintenance turf such as athletic fields, home lawns, or golf courses. Prior to the release of Merion in 1947, common Kentucky bluegrasses were the most prevalent type used for turf. The common type bluegrasses, predominately adapted to the Midwest region of the United States, are useful for soil conservation, pastures, and lower maintenance turf. This is due to their early maturity, moderately quick establishment, good stress tolerance, and the ability to survive dry summers in a dormant state. However, these common-type bluegrasses can suffer extensive turf loss from the fungal disease leaf spot and melting out (caused by *Drechslera poae*) under close mowing in humid environments. Merion Kentucky bluegrass, discovered by Joseph Valentine in the early 1930s, had better leaf spot resistance and greatly increased the usefulness of Kentucky bluegrass as a turf in regions with a humid, temperate climate. Turf-type Kentucky bluegrasses have a lower, more prostrate growth habit, respond well to higher maintenance

regimes, tolerate closer mowing, and have greater resistance to leaf spot diseases than common type bluegrasses.

Since Kentucky bluegrass reproduces through an asexual process called apomixis, improvement in cultivar performance is challenging. The advantage of apomixis is that it also provides the opportunity to produce true-to-type seed from superior plants generation after generation. Over the past several decades, more than 200 cultivars of Kentucky bluegrass have been released. Kentucky bluegrass cultivars have been developed through a number of approaches that include: i) selection of naturalized ecotypes or highly apomorphic plants found in old pastures or turfs; ii) blending of highly apomorphic single plants (called composites); and iii) selection of single, highly apomorphic plants from breeding programs using intraspecific and interspecific hybridization.

Kentucky bluegrass can exhibit poor performance during summer months, especially in the transition zone and southern states due to heat and drought stress as well as insect and disease pressure. Currently, Rutgers has been utilizing interspecific hybridization for the development of Texas bluegrass (*Poa arachnifera* Torr.) x Kentucky bluegrass hybrids to try to incorporate valuable traits from Texas bluegrass into Kentucky bluegrass. Texas bluegrass, native to Texas and parts of Oklahoma, is a dioecious species that is more tolerant of heat and drought stress conditions than Kentucky bluegrasses. Texas bluegrass x Kentucky bluegrass crosses were made as early as 1908 by George H. Oliver who noticed a wide variation in first-generation hybrids including plants that were more heat and drought tolerant and more productive than Kentucky bluegrass (Vinall and Hein, 1937). Hybrid evaluation for fertile, highly apomorphic offspring with improved performance is currently un-

¹Assistant Professor, Associate Extension Specialist in Turfgrass Management, Research Professor, Research Professor, Turfgrass Research Farm Supervisor, Graduate Assistant, Principal Laboratory Technician, Principal Laboratory Technician, and Soils and Plants Technician, respectively, New Jersey Agricultural Experiment Station, Cook College, Rutgers, The State University of New Jersey, New Brunswick, NJ 08901-8520.

derway at Rutgers. This breeding strategy of crossing female Texas bluegrass plants with Kentucky bluegrass could expand the adaptation of Kentucky bluegrass through transition zone areas and into southern states where better heat and drought tolerance is needed for better performance.

The Kentucky bluegrass improvement program at Rutgers involves extensive field evaluation of collections from the United States, Europe, and Asia, new material developed in the breeding program, as well as cultivars and selections developed by other breeders. Recent collection trips to Poland, Bulgaria, China, Romania, Germany, Portugal, Finland, France, Spain, Norway, the Slovac Republic, Uzbekistan, and Kyrgyzstan have enhanced the diversity of germplasm incorporated into the Kentucky bluegrass hybridization program. In addition, the turfgrass research program at Rutgers participates in the National Turfgrass Evaluation Program (NTEP), which is sponsored by the Beltsville Agricultural Research Center and the National Turfgrass Federation, Inc.

PROCEDURES

Eleven trials were seeded in September between 1996 and 2000 at North Brunswick, Adelphia, or Pittstown, NJ (Tables 1 to 11). Two medium-low maintenance tests were established at Pittstown in 1998 (Table 5) and at Adelphia in 1999 (Table 8). The other tests were conducted under medium-high maintenance regimes. The soils at the three research farms are moderately fertile and fairly well drained.

Entries in each test were sown by hand using a maximum of 0.53 oz of seed per 3 X 5 ft plot (2.2 lb/1000 ft²). An unplanted 6-inch border was left around each plot. Each test was arranged in a randomized complete block design with three replications. Annual nitrogen (N) applied and mowing heights for each trial are presented in Table 12. The amount of N applied varied between tests to permit the evaluation of characteristics known to respond to N level. No single N application exceeded 1.0 lb/1000 ft². Mowing was frequent enough (two or three times per week during active growth) to avoid excessive defoliation and the accumulation of clippings. Reel mowers were used to maintain a 1.5 inch height of cut, while rotary mowers were employed at a higher cut.

After establishment, summer annual weeds were controlled in all tests using a spring application of dithiopyr (Dimension), and broadleaf weeds were controlled on the 1998 trial at North Brunswick (Table

3) by an autumn application of Confront. No other pesticides were applied. Soil pH was maintained between 6.0 and 6.5 with agricultural limestone, depending on soil test results. Tests were irrigated during establishment and also when needed to avoid severe drought stress. The medium-low maintenance test at Pittstown (Table 5) received irrigation when soil moisture was extremely low. The medium-low maintenance test at Adelphia (Table 8) was irrigated only during establishment.

All tests were rated frequently throughout the growing season for turf quality (e.g., color, brightness, leaf texture, density, uniformity, and amount of disease and insect damage). Other characteristics were evaluated separately when differences between entries were evident. These characteristics included spring green-up (Tables 1 to 3, 6, 9, and 11), winter color (Tables 9 and 10), leaf spot (Tables 4 and 7), steminess (Tables 4, 7, 10, and 11), genetic color (Tables 9 and 10), establishment (Tables 9 to 11), heat tolerance (Table 9), billbug (*Sphenophorus* spp.) damage (Table 5), vigor (Table 11), height (Table 10), density (Table 9), and *Poa annua* L. invasion (Table 6). All ratings were based on a 1 to 9 scale, where 9 represented the most favorable turf quality or desirable turf characteristic. Ratings were conducted by a number of researchers throughout the season to reduce individual preferences toward a particular trait.

RESULTS

Turf Evaluation Trials

Results are presented in Tables 1 through 11. Entries are ranked according to their overall (multi-year) quality average. Tables 9 and 10 include all the entries of the 2000 Medium-High Maintenance Kentucky Bluegrass Trial sponsored by NTEP. Additional characteristics observed in various tests (i.e., spring green-up, winter appearance, leaf spot, steminess, establishment, and genetic color) are discussed below. Other characteristics such as heat tolerance, vigor, plant height, billbug damage, density, and *Poa annua* invasion are also reported.

Spring Green-Up

These traits are obvious during late winter or early spring and reflect the wide range of genetic diversity present within Kentucky bluegrass (Tables 1 to 3, 6, 9, 11). Cultivars exhibiting early spring green-up in a number of trials include Kenblue, Wildwood, Blackstone, and Langara. Some experimental se-

lections with early spring green up include A97-1409, A91-702, and SRX 2284. Cultivars and selections with slow spring green-up include Midnight, PST-731, J-1838, and Quantum Leap (Tables 1, 4, and 9). Many cultivars and selections in the evaluation trials are adapted to New Jersey and the mid-Atlantic region (37°N to 42°N latitude) and typically have early spring green-up. The mid-Atlantic region is characterized by shorter days and warmer temperatures during the growing season, compared to the higher latitudes and cool climates of Scandinavia (60°N latitude). Due to an increase in leaf elongation that occurs in response to increases in temperature and daylength (Parsons and Robson, 1980), cultivars adapted to this region may green up earlier in the spring. Other cultivars and selections adapted to higher latitudes may need a more dramatic change in daylength before spring growth is initiated.

Leaf Spot

Leaf spot is a foliar disease that affects Kentucky bluegrass most dramatically during the cloudy wet weather of spring. Differences in tolerance to this disease were evident among many of the cultivars and selections tested (Tables 4 and 7). Leaf spot disease is often associated with plants that have low carbohydrate levels in the leaf tissue. Some cultivars with early spring green-up (increased shoot elongation) may lose more carbohydrates through mowing, and are thus more susceptible to leaf spot (Smiley, 1992). Other cultivars or selections that do not actively elongate as early and are low growing cultivars (e.g., Midnight, Brilliant, Langara, and America) do not lose as many carbohydrates during mowing, and this may provide an increased resistance to leaf spot. Other cultivars and selections with good resistance to leaf spot include Boutique, Monte Carlo, A97-1409, and Royale. Cultivars and selections exhibiting susceptibility to leaf spot include Eagleton, Voyager, RSP, and Huntsville (Table 7).

Steminess

Steminess is prevalent in spring when some cultivars and selections of Kentucky bluegrass produce visible panicles and seed heads, even when closely mowed (Tables 4, 7, 10, and 11). Cultivars with a large number of reproductive tillers (including Baron and Dragon) appear stemmy, which detracts from turf quality in the late spring. Cultivars that produce few reproductive tillers in turf plots include Moon Shadow, Langara, Northstar, PST-739, RSP, and Lakeshore (Tables 4 and 10).

Establishment

Rapid establishment (or seedling vigor, Tables 9 to 11) is important to consumers, sod growers, and other turf professionals who establish Kentucky bluegrass turfs from seed. Kentucky bluegrass is one of the slowest cool-season turfgrasses to establish a mature stand. Seedling vigor can be influenced by factors such as genetics, seed quality, environment, management practices, and after-ripening dormancy. After-ripening dormancy, which occurs with freshly harvested seed, delays germination of the seed under conditions of warm days and nights. Thus, plantings during warm days and warm nights that utilize recently harvested seed lots may be exhibiting varying degrees of after-ripening dormancy rather than genetic differences in seedling vigor between cultivars. This dormancy is broken during storage at warm temperatures and is less pronounced if germination occurs during periods with cool nights and frequent rainfall.

Genetic Color

Genetic color is one characteristic that demonstrates the broad genetic diversity that exists in Kentucky bluegrass. Professional sod growers, landscapers, and consumers are interested in the intensity of a cultivar's green color during the growing season (Tables 9 and 10) or in the retention of its green color during the winter months (Tables 9 and 10). Cultivars such as Moonlight, Midnight, and Rugby II and selections such as A98-15, A98-155, PST B5-89, and A98-2038 are among the darkest green entries compared to cultivars such as Washington, Kenblue, Barzan, Wellington, Lilly, and Julius, which have a brighter, medium green color.

SUMMARY

Kentucky bluegrass is grown for many uses under a diverse range of soil, environmental, and management conditions. As a result, there is a demand for cultivars that produce a durable, high quality turf for an assortment of uses under a broad range of conditions. Improved resistance to important disease and insect pests, heat, drought, close mowing, shade, and wear is needed in cultivars that are expected to perform well in many situations.

ACKNOWLEDGMENTS

New Jersey Agricultural Experiment Station Publication No. E-12264-3-02. This work was conducted

as part of NJAES Project No. 12264, supported by the New Jersey Agricultural Experiment Station, State, and Hatch Act funds, the Rutgers Center for Turfgrass Science, other grants, and gifts. Additional support was received from the United States Golf Association-Golf Course Superintendents Association of America Research Fund, the National Turfgrass Evaluation Program, and the New Jersey Turfgrass Association.
