

# 2005 RUTGERS Turfgrass Proceedings

THE NEW JERSEY TURFGRASS ASSOCIATION

In Cooperation With

RUTGERS COOPERATIVE RESEARCH & EXTENSION  
NEW JERSEY AGRICULTURAL EXPERIMENT STATION  
RUTGERS, THE STATE UNIVERSITY OF NEW JERSEY  
NEW BRUNSWICK

Distributed in cooperation with U.S. Department of Agriculture in furtherance of the Acts of Congress on May 8 and June 30, 1914. Rutgers Cooperative Research & Extension works in agriculture, family and community health sciences, and 4-H youth development. Dr. karyn Malinowski, Director of Extension. Rutgers Cooperative Research & Extension provides education and educational services to all people without regard to race, color, national origin, gender, religion, age, disability, political beliefs, sexual orientation, or marital or family status. (Not all prohibited bases apply to all programs). Rutgers Cooperative Research & Extension is an Equal Opportunity Program Provider and Employer.

# **2005 RUTGERS TURFGRASS PROCEEDINGS**

**of the**

## **New Jersey Turfgrass Expo December 6-8, 2005 Trump Taj Mahal Atlantic City, New Jersey**

The Rutgers Turfgrass Proceedings is published yearly by the Rutgers Center for Turfgrass Science, Rutgers Cooperative Extension, and the New Jersey Agricultural Experiment Station, Cook College, Rutgers, The State University of New Jersey in co-operation with the New Jersey Turfgrass Association. The purpose of this document is to provide a forum for the dissemination of information and the exchange of ideas and knowledge. The proceedings provide turfgrass managers, research scientists, extension specialists, and industry personnel with opportunities to communicate with co-workers. Through this forum, these professionals also reach a more general audience, which includes the public.

This publication includes lecture notes of papers presented at the 2005 New Jersey Turfgrass Expo. Publication of these lectures provides a readily available source of information covering a wide range of topics and includes technical and popular presentations of importance to the turfgrass industry.

This proceedings also includes research papers that contain original research findings and reviews of selected subjects in turfgrass science. These papers are presented primarily to facilitate the timely dissemination of original turfgrass research for use by the turfgrass industry.

Special thanks are given to those who have submitted papers for this proceedings, to the New Jersey Turfgrass Association for financial assistance, and to Barbara Fitzgerald and Marlene Karasik for administrative and secretarial support.

Dr. Ann Brooks Gould, Editor  
Dr. Bruce B. Clarke, Coordinator

## PERFORMANCE OF BENTGRASS CULTIVARS AND SELECTIONS IN NEW JERSEY TURF TRIALS

Matthew J. Koch, Eric N. Weibel, Dirk A. Smith, William K. Dickson, Joseph B. Clark,  
Stacy A. Bonos, James A. Murphy, Bruce B. Clarke, and William A. Meyer<sup>1</sup>

Bentgrass species have the distinct ability to form very dense, uniform, and fine textured surfaces under an extremely low height of cut. Because of these unique qualities, bentgrasses can be used in specialized, high maintenance areas such as golf course fairways, tees, and putting greens. Some of the more popular species used for turf include creeping bentgrass (*Agrostis palustris* Huds.; synonym = *A. stolonifera* L.), colonial bentgrass (*A. tenuis* L. or *A. capillaris* L.), velvet bentgrass (*A. canina* L.), and less frequently, highland or dryland bentgrass (*A. castellana* Boiss. & Reut.). Creeping and velvet bentgrasses are best conditioned for the very low cutting heights required for golf course greens in the United States and other regions of the world.

Creeping bentgrass is highly stoloniferous and has prostrate growth, so this grass persists well under very low mowing heights. This species is highly adapted to both cool, temperate as well as warm, humid regions of the United States, making it the most popular species used on golf course putting greens. Its vigorous, spreading growth habit also contributes to its use. In 1954, H.B. Musser released Penncross, the first seeded variety of creeping bentgrass (Musser, 1959). Since that time, breeding efforts have markedly improved creeping bentgrass varieties to withstand the increasing demands of the game of golf, addressing the need for better turf quality, darker green color, improved shoot density, and improved traffic tolerance and recuperative ability, as well as increased disease and stress tolerance compared to older varieties.

Colonial bentgrass, also referred to as browntop, has traditionally been used as a lawn grass in the areas of northern Europe and New Zealand that have mild (cool and humid) summers. Compared to creeping bentgrass, colonial bentgrass has a finer leaf texture and a more upright and less aggressive spread-

ing growth habit. In addition, this bentgrass is generally better adapted for fairway or tee use in the warmer summer climates of the United States and performs best in New Jersey when mowed no lower than 3/8 of an inch. Compared to creeping bentgrass, colonial bentgrass typically has a brighter green color, better color retention during cool weather, better resistance to dollar spot (caused by *Sclerotinia homoeocarpa*), and better wear tolerance. Colonial bentgrass is more susceptible, however, to brown patch (caused by *Rhizoctonia solani*). While this disease is not lethal, the playability of golf courses may be affected if brown patch is not controlled. Current breeding efforts include improving the tolerance of colonial bentgrass to this disease.

Velvet bentgrass forms the finest-textured and most dense turf of the bentgrasses and can nearly resemble green velvet when managed properly. It spreads mainly through profuse production of erect tillers with short stolons. This grass can tolerate very close mowing, heat, cold, and shade, and is one of the most drought resistant of the bentgrasses used for turf (Skogley, 1973). Due to the density and vigor of this turf, even under very low mowing conditions, velvet bentgrass has been shown to be extremely effective at preventing the encroachment of the most prolific weed on a golf course, *Poa annua*. The spread of velvet bentgrass via stolons is more aggressive than colonial bentgrass, but not as strong as with creeping bentgrass. Velvet bentgrass can form excessive thatch, especially at higher fertility rates and higher cutting heights, and can thus become problematic if not maintained properly. This species is also susceptible to red thread (caused by *Laetisaria fuciformis*) and copper spot (*Gloeocercospora sorghi*), but has good resistance to dollar spot and brown patch. Seedlings of velvet bentgrasses are susceptible to Pythium seedling root rot during establishment. Velvet bentgrass has not

<sup>1</sup>Graduate Assistant, Head Soils and Plants Technician, Principle Laboratory Technician, Turfgrass Research Farm Supervisor, Principle Laboratory Technician, Assistant Professor, Extension Specialist in Turfgrass Management, Extension Specialist in Turfgrass Pathology, and Research Professor, respectively, New Jersey Agricultural Experiment Station, Cook College, Rutgers, The State University of New Jersey, New Brunswick, NJ 08901-8520.

been used extensively for high maintenance turf, largely because its range of adaptation has not been well recognized. Selections of velvet bentgrass have persisted for many years in trials under New Jersey growing conditions. As recent research at Rutgers indicates, the species may one day serve as a viable alternative to creeping bentgrass for use on golf course greens as proper cultural management inputs are developed. Early indications show that a lower fertility requirement is needed to maintain a velvet bentgrass turf when compared to one with creeping bentgrass under the same conditions.

The New Jersey Agricultural Experiment Station participates in the National Turfgrass Evaluation Program (NTEP), which evaluates many species of turfgrass, including bentgrasses, throughout the United States. The Rutgers turfgrass breeding program conducts extensive field evaluations of collections and new material developed in the improvement program, many of which are a result of recent collection trips within the United States and throughout Europe and Asia. Collections from Norway, Sweden, Spain, Portugal, France, Finland, Switzerland, Scotland, Italy, Greece, Poland, Holland, Bulgaria, Romania, Croatia, China, and the Slovak Republic, which are the centers of origin for many turf species used in the United States, serve to enhance the genetic diversity of the germplasm used in this breeding program. The Rutgers turfgrass breeding program focuses on improving turfgrasses for overall quality, color, density, uniformity, texture, disease resistance, salt tolerance, traffic tolerance, and many other aspects of a turf to be grown for a variety of purposes.

## PROCEDURES

Bentgrass evaluation trials were established at the Rutgers Horticultural Research Farm II in North Brunswick, NJ in the fall of 2001 (Tables 1 to 3), 2002 (Tables 4 and 5), 2003 (Tables 7 and 9), and 2004 (Tables 10 and 11). Two of the trials planted in the fall of 2003 (Tables 6 and 8) included all entries of the 2003 National Bentgrass Test coordinated by NTEP. Trials were established on a modified Nixon loam, except the 2003 NTEP putting green trial (Table 6), which was seeded on a sand root zone built to USGA specifications. Plot size was 3 X 5 ft for all trials, except the 2003 NTEP trials (greens and fairway/tee) which were 4 X 6 ft. Plots were hand-seeded at a rate of approximately 0.5 lb/1000 ft<sup>2</sup>. All tests were arranged in a randomized complete block design with three replications.

All sites were well drained and openly exposed to both sunlight and air circulation (with the exception of the 2003 NTEP putting green trial, which had enclosed air circulation). The annual rate of nitrogen applied, mowing height, cultivation/topdressing practices, and pesticide applications for each test are presented in Table 12. The putting green tests were mowed five to six times per week during periods of active growth with a triplex or walk-behind reel mower equipped to collect clippings. The fairway tests were mowed and clippings were removed three times per week with a triplex reel mower during periods of active growth. Soil pH was maintained in the range of 6.0 to 6.5 with agricultural limestone. All tests were irrigated to avoid drought stress.

Plots were evaluated frequently during the growing season for overall turf quality (i.e., turf density, texture, uniformity, color, growth habit, and degree of damage due to diseases and insects). Turf quality, spring green-up, color, density, and disease were rated on a 1 to 9 scale, where 9 represented the most desirable turf characteristic. Disease ratings included brown patch (Tables 7 and 11), dollar spot (Tables 7, 9, and 11), copper spot (Table 10), and red leaf spot (Tables 5 and 10). All data were subjected to analysis of variance. Means were separated using Fisher's protected least significant difference (LSD) means separation test.

## RESULTS AND DISCUSSION

### Turf Quality Evaluations

Entries in Tables 1 through 9 are ranked according to their overall multi-year quality average. Entries in Tables 10 and 11 are ranked according to their turf quality average in 2005. Throughout the years, a few varieties in each bentgrass species have stood out among the rest. For creeping bentgrasses maintained at a putting green height of cut, Authority, Declaration, Tyee, and Shark all performed very well, whereas the turf quality of Penncross, Providence, Viper, and Crenshaw was poor. At a fairway height, the turf quality was excellent for Authority and Declaration and poor for Providence, Southshore, Penncross, and Crenshaw.

Velvet bentgrasses are also rated for turf quality every year. In trials evaluated in 2005, varieties such as Venus, Greenwich, and Villa were rated among the best in every putting green test in which they were entered, whereas ISC comp, IVC comp, SRX 7EW

88-34, and SR 7200 were rated among the worst under a 1/8 inch height of cut. Interestingly, cultivar SR 7200, along with Greenwich, performed the best at a fairway height of cut. Velvet bentgrass cultivars Barbella and PST-VE52 Bulk were among the worse performers on fairways (Table 9).

Turf quality was also rated for colonial bentgrass. Since this species is best suited for a slightly higher height of cut than a putting green, it was no surprise that colonial bentgrass cultivars did not perform very well when cut to 1/8 inch. The cultivar Tiger II received the lowest score for colonial bentgrasses in putting green trials. Fairway heights are more suited for this species, and cultivars 9ER Bulk-5, SRX 781-22, 9BNC-2001, EWTR comp, HCG comp, and PST-SYN-9BC3 all received high scores, whereas SRX 781-21 did not.

### Dollar Spot

While potentially one of the more damaging diseases on golf courses in New Jersey, dollar spot can be easily controlled with the use of fungicides. Unfortunately, disease control can be expensive because dollar spot occurs so frequently, and resistance of the causal agent to fungicides has become more prevalent. Breeding for dollar spot resistance in bentgrass is an important objective of the Rutgers breeding program. Although velvet and colonial bentgrasses typically are more resistant to dollar spot, results from recent trials indicate that significant improvements in creeping bentgrasses have been made. For example, in the 2003 putting green trial (Table 7), the creeping bentgrasses Declaration, L-93, and Kingpin had the highest ratings for resistance to dollar spot, whereas disease resistance of Crenshaw and Independence was poor. In the 2003 fairway trial (Table 9), creeping bentgrasses Benchmark and Declaration as well as colonial bentgrasses PST-9R3 and PST-9VN all rated well for resistance. Ratings for disease resistance in SRX 1H Blue and Century creeping bentgrasses, however, was low. Colonial bentgrasses 9108-1 & 5 and LDP Comp rated the highest in the 2004 fairway trial, while the most resistant creeping bentgrasses included SRX 1WM231 and Declaration (Table 11). The most susceptible selections included Penncross and Century creeping bentgrasses.

### Brown Patch

Velvet bentgrass is the most tolerant of brown patch among the bentgrass species used for turf, and creeping bentgrass is typically more resistant than colonial bentgrass. For example, in the 2004 fairway trial (Table 11), velvet bentgrasses PST-EVX-Bulk, Villa, IS-AP14, and the creeping bentgrass Shark were among the entries most tolerant of this disease. The least tolerant entries included the colonial bentgrasses SRX 781-21 and SRX 780-19 and the creeping bentgrasses Penncross and Providence. Much progress has been made in breeding colonial bentgrasses for improved resistance to this disease. The colonial bentgrasses BCD comp and 9111-6-12, specifically selected for brown patch resistance, were much more tolerant of this disease than commonly used cultivars such as SR 7150, SR 7100, Alister, and Tiger II.

### Red Leaf Spot

Ratings for the disease red leaf spot, caused by the fungus *Drechslera erythrosipa*, were completed on the 2002 fairway trial in June (Table 5) and the 2004 putting green trial in July (Table 10). Compared to colonial bentgrass varieties, velvet and creeping bentgrasses typically rate much higher for resistance to this disease. The highest scoring cultivars in the 2002 trial included the creeping bentgrasses CIS AP-12 and SRX 1G 32 as well as the velvet bentgrasses Venus and SR 7200. The lowest rated entries were the colonial bentgrass varieties SRX 7MOBB and SRX 7EE5. In the 2004 trial, the creeping bentgrass SRX 146-12, colonial bentgrass PST-9PIN, and velvet bentgrasses Greenwich and VE3 Comp were the most resistant to red leaf spot, whereas Penncross and Seaside II creeping bentgrasses did not perform well.

### Copper Spot

In the Northeast, copper spot commonly occurs during late spring due to the warm, wet conditions that are typical that time of year. The causal agent of this disease, *Gloeocercospora sorghi*, is a fungus that produces 3- to 4-inch red-brown patches on the turf. In the 2004 putting green trial (Table 10), the colonial bentgrass cultivars were typically more resistant to

this disease than both the velvet and creeping bentgrasses. The top ranking entries for this rating were colonial bentgrasses Glory and Alister, and the poorest performers were the creeping bentgrasses FDS2 Comp and SRX 1WM236.

### **Spring Green-Up and Fall Dormancy**

Spring green-up data was collected for both 2003 putting green trials (Tables 6 and 7). Compared to the velvet bentgrasses, the creeping bentgrasses generally green-up better in the spring. Several creeping bentgrass entries that possessed early green-up qualities included the cultivars Declaration (Tables 6 and 7) and Penn G-2 (Table 6). Villa velvet bentgrass had the best rating among all of the velvet bentgrass entries. The lowest ratings went to the bentgrasses Penncross and Crenshaw and the velvet bentgrass Greenwich. Shark and Authority creeping bentgrasses had the best ratings for spring green-up in the 2003 putting green trial, whereas SR 1119 and Crenshaw had the poorest (Table 7).

In contrast to spring green-up, fall dormancy was rated for the 2003 NTEP fairway trial (Table 8). The cultivars showing the least dormancy included PST-OEB, Bengal, and Pennlinks creeping bentgrasses, whereas the cultivars showing the most fall dormancy were IS-AT 7, EWTR, and Bardot colonial bentgrasses.

### **Establishment**

The 2004 putting green and fairway trials were given numerical values to evaluate how well each variety established from seed. The creeping bentgrass varieties SRX 1BL2G, Penneagle II, T-1, Southshore, Putter, Providence, and Seaside II, the velvet bentgrass Greenwich, and the colonial bentgrass Glory all ranked very high in the putting green trial (Table 10). Century creeping bentgrass and EVA Comp velvet bentgrass had the worst establishment, whereas the colonial varieties 9114-1-6, 9118-1-6b, 9113-1&5, and 9107-6-12 were the slowest to establish in the fairway trial (Table 11).

### **Scalping**

Scalping was evaluated in July for the 2003 NTEP fairway trial (Table 8). Most varieties had little to no scalping damage at the 3/8-inch cutting height. The poorest performers for this characteristic included Declaration, SR 1150, IS-AP 14, and LS-44 creeping bentgrasses. The damage due to scalping for

the remainder of the varieties in this test were at acceptable levels.

### **Density and Leaf Texture**

Turfgrass density and leaf texture were measured for the 2003 NTEP putting green and fairway trials in October. Leaf texture is a measure of the width of the leaves, and density is a number given to quantify the number of shoots per unit area. The velvet bentgrasses ranked the highest for these traits compared to the creeping or colonial bentgrasses. In the fairway trial, SR 7200 velvet bentgrass had the highest possible rating for both density and leaf texture, and Shark, MacKenzie, and Authority performed the best of the creeping bentgrasses (Table 8). Entries with the poorest turf density and leaf texture ratings were Seaside, Penncross, Princeville, and Pennlinks creeping bentgrasses. In the putting green trial (Table 6), velvet bentgrasses Villa, Legendary, Venus, Vesper, and SR 7200 all received the highest scores for these characteristics, while Penncross, Pennlinks II, and Penneagle creeping bentgrasses rated the poorest.

### **Genetic Color**

Genetic color was rated in October on the 2003 NTEP putting green and fairways trials. High numbers were assigned to plots that had a dark green color while lighter green or yellowish turf received lower numbers. Typically, velvet and colonial bentgrasses have a light green color, whereas creeping bentgrasses have a darker green color. In some cases, creeping bentgrass cultivars exhibit an almost blue-green coloration. In the putting green trial (Table 6), the creeping bentgrasses T-1, Alpha, and Crenshaw were the darkest green, and the velvet bentgrasses Venus and SR 7200 and the creeping bentgrasses Century, Penneagle, and Penncross were lighter in color. Pennlinks, Bengal, and PST-OEB creeping bentgrasses were ranked the best in the fairway trial (Table 8). The lowest numbers were assigned to IS-AT 7, EWTR, and Bardot creeping bentgrass varieties.

### **ACKNOWLEDGMENTS**

New Jersey Experiment Station Publication No. E-12180-24-05. This work was conducted as part of NJAES Project No. 12264, supported by the Rutgers Center for Turfgrass Science, the New Jersey Agricultural Experiment Station, State and Hatch Act funds, other grants and gifts. Additional support was

received from the United States Golf Association-Golf Course Superintendents Association of America Research Fund, New Jersey Turfgrass Association, the New Jersey Turfgrass Foundation and the National Turfgrass Evaluation Program.
