Rutgers Cooperative Extension

2006 RUTGERS TURFGRASS PROCEEDINGS

of the

New Jersey Turfgrass Expo December 5-7, 2006 Trump Taj Mahal Atlantic City, New Jersey

The Rutgers Turfgrass Proceedings is published yearly by the Rutgers Center for Turfgrass Science, Rutgers Cooperative Extension, and the New Jersey Agricultural Experiment Station, School of Environmental and Biological Sciences, Rutgers, The State University of New Jersey in cooperation with the New Jersey Turfgrass Association. The purpose of this document is to provide a forum for the dissemination of information and the exchange of ideas and knowledge. The proceedings provide turfgrass managers, research scientists, extension specialists, and industry personnel with opportunities to communicate with co-workers. Through this forum, these professionals also reach a more general audience, which includes the public.

This publication includes lecture notes of papers presented at the 2006 New Jersey Turfgrass Expo. Publication of these lectures provides a readily avail-

able source of information covering a wide range of topics and includes technical and popular presentations of importance to the turfgrass industry.

This proceedings also includes research papers that contain original research findings and reviews of selected subjects in turfgrass science. These papers are presented primarily to facilitate the timely dissemination of original turfgrass research for use by the turfgrass industry.

Special thanks are given to those who have submitted papers for this proceedings, to the New Jersey Turfgrass Association for financial assistance, and to Barbara Fitzgerald and Marlene Karasik for administrative and secretarial support.

Dr. Ann Brooks Gould, Editor
Dr. Bruce B. Clarke, Coordinator

PERFORMANCE OF BENTGRASS CULTIVARS AND SELECTIONS IN NEW JERSEY TURF TRIALS

Matthew J. Koch, Eric N. Weibel, Dirk A. Smith, Tracy J. Lawson, William K. Dickson, Joseph B. Clark, Stacy A. Bonos, James A. Murphy, Bruce B. Clarke, and William A. Meyer¹

Bentgrass species have the distinct ability to form very dense, uniform, and fine textured surfaces under an extremely low height of cut. Because of these unique qualities, bentgrasses can be used in specialized, high maintenance areas such as golf course fairways, tees, and putting greens. There are three bentgrass species typically used for turf. These include creeping bentgrass (*Agrostis palustris* Huds.; synonym = *A. stolonifera* L.), colonial bentgrass (*A. tenuis* L. or *A. capillaris* L.), and velvet bentgrass (*A. canina* L.). Used less frequently, highland or dryland bentgrass (*A. castellana* Boiss. & Reut.) can be options for turf in stressful areas. Creeping and velvet bentgrasses are best conditioned for the very low cutting heights required for golf course greens in the United States. Colonial bentgrass, which does best with a slightly greater height of cut, is better suited for fairways in temperate areas of the United States.

Creeping bentgrass, which is highly stoloniferous and has a prostrate growth habit, persists under very low mowing heights (up to 1/8 of an inch or less). Since this species is well adapted to both cool-temperate as well as warm-humid regions of the United States, it is the most popular species used on golf course putting greens. Its vigorous, spreading growth habit also contributes to its ability to repair damaged areas quickly. In 1954, H.B. Musser released Penncross, the first seeded variety of creeping bentgrass (Musser, 1959). Since that time, breeding efforts have markedly improved creeping bentgrass varieties to withstand the increasing demands of the game of golf, addressing the need for better turf quality, darker green color, improved shoot density, improved traffic tolerance and recuperative ability, and increased disease and stress tolerances. Dollar spot (caused by the fungus *Sclerotinia homoeocarpa*) is one of the main disease problems of close-cut creeping bentgrass.

Colonial bentgrass, also referred to as brown top, has traditionally been used as a lawn and golf course grass in areas of Northern Europe and New Zealand that have mild (cool and humid) summers. Compared to creeping bentgrass, Colonial bentgrass has a finer leaf texture, a more upright growth habit, and spreads less aggressively. In addition, this bentgrass is generally better adapted for fairway or tee use in the warmer summer climates of the United States. Colonial bentgrass performs best in New Jersey when mowed no lower than 3/8 of an inch. Compared to creeping bentgrass, colonial bentgrass has a brighter green color and better color retention during cool weather, resistance to dollar spot, and wear tolerance. However, this turfgrass is much more susceptible to brown patch (caused by the fungus *Rhizoctonia solani*). While brown patch is not lethal, the playability of golf courses may be affected if the disease is not controlled. Current breeding efforts include improving the tolerance of colonial bentgrasses to this disease.

Velvet bentgrass forms the finest-textured and most dense turf of the bentgrasses and can nearly resemble green velvet when managed properly. It spreads by profusely producing erect tillers with short stolons. This grass can tolerate very close mowing, heat, cold, and shade, and is one of the most drought resistant of the bentgrasses used for turf (Skogley, 1973). Due to the density and vigor of this turf, even under very low mowing conditions, velvet bentgrass is less susceptible to the encroachment of *Poa annua*, the most prolific weed on a golf course. The spread of velvet bentgrass via stolons is more aggressive than colonial bentgrass, but is less aggressive than creeping bentgrass. Velvet bentgrass can form excessive thatch, especially at higher fertility and cutting heights, and can thus become problematic if not maintained properly. This species is also suscep-

¹Graduate Assistant, Head Soils and Plants Technician, Principle Laboratory Technician, Principle Laboratory Technician, Turfgrass Research Farm Supervisor, Principle Laboratory Technician, Assistant Professor, Extension Specialist in Turfgrass Management, Extension Specialist in Turfgrass Pathology, and Research Professor, respectively, New Jersey Agricultural Experiment Station, School of Environmental and Biological Sciences, Rutgers, The State University of New Jersey, New Brunswick, NJ 08901-8520.

table to red thread (caused by *Laetisaria fuciformis*) and copper spot (caused by *Gloeocercospora sorghi*), but has good resistance to dollar spot and brown patch. Seedlings of velvet bentgrass are susceptible to Pythium root rot during establishment.

During the colder weather, velvet bentgrass turf will turn a dark purple color and will take longer than the other bentgrass species to green-up in the spring. Velvet bentgrass has not been used extensively for high maintenance turf, largely because its range of adaptation has not been well characterized. Selections of velvet bentgrass have persisted for many years in trials under New Jersey growing conditions. Recent research at Rutgers indicates that the species may one day serve as a viable alternative to creeping bentgrass for use on golf course greens, as long as proper cultural management inputs are implemented. Early indications are that a lower fertility requirement is needed to maintain a velvet bentgrass turf when compared to one with creeping bentgrass under the same conditions. Some of the major breeding objectives for velvet bentgrass include tolerance to copper spot, Pythium root rot, and wear.

The New Jersey Agricultural Experiment Station participates in the National Turfgrass Evaluation Program (NTEP), which evaluates many species of turfgrass, including bentgrass, at various locations throughout the United States. The Rutgers turfgrass breeding program conducts extensive field evaluations of collections and new material developed in the improvement program, many of which were recently collected throughout the United States, Europe, and Asia. Collections from Norway, Sweden, Spain, Portugal, France, Finland, Switzerland, Scotland, Italy, Greece, Poland, Holland, Bulgaria, Romania, Croatia, China, and the Slovak Republic, which are the centers of origin for many turf species used in the United States, serve to enhance the genetic diversity of the germplasm used in this breeding program. The Rutgers turfgrass breeding program focuses on improving turfgrasses for overall quality, color, density, uniformity, texture, disease resistance, salt tolerance, traffic tolerance, and many other aspects of turf grown for a variety of purposes.

PROCEDURES

Bentgrass evaluation trials were established at the Rutgers Horticultural Research Farm II in North Brunswick, NJ in the fall of 2002 (Tables 1 and 2), 2003 (Tables 3 through 5), 2004 (Tables 6 and 7), and 2005 (Tables 8 and 9). Two of the trials planted

in the fall of 2003 (Tables 3 and 4) included all entries of the 2003 National Bentgrass Test coordinated by NTEP. Trials were established on a modified Nixon loam, except the 2003 NTEP putting green trial (Table 3), which was seeded on a sand root-zone built to USGA (1993) specifications. Plot size was 3 x 5 ft for all trials, except the 2003 NTEP trials (greens and fairway/tee) which were 4 x 6 ft. Plots were hand-seeded at a rate of approximately 0.5 lb seed/1000 ft². All tests were arranged in a randomized complete block design with three replications.

All sites were well drained and openly exposed to both sunlight and air circulation (with the exception of the 2003 NTEP putting green trial, which had reduced air circulation due to a depressed site location surrounded by trees). The annual rate of nitrogen applied, mowing height, cultivation/topdressing practices, and pesticide applications for each test are presented in Table 10. The putting green tests were mowed five to six times per week during periods of active growth with a triplex or walk-behind reel mower equipped to collect clippings. The fairway tests were mowed and clippings were removed three times per week with a triplex reel mower during periods of active growth. Soil pH was maintained in the range of 6.0 to 6.5 with agricultural limestone. All tests were irrigated to avoid drought stress.

Plots were evaluated frequently during the growing season for overall turf quality (i.e., turf density, texture, uniformity, color, growth habit, and damage due to diseases and insects). Turf quality, wear tolerance, spring green-up, color, density, and disease were rated on a 1 to 9 scale, where 9 represents the most desirable turf characteristic. Disease ratings included brown patch (Tables 4, 5, 7, 8, and 9), dollar spot (Tables 4, 5, 6, and 9), and copper spot (Table 8). All data were subjected to analysis of variance. Means were separated using Fisher's protected least significant difference (LSD) means separation test.

RESULTS AND DISCUSSION

Turf Quality Evaluations

Entries in Tables 1 through 7 and 9 are ranked according to their overall multi-year quality average. Entries in Table 8 are ranked by turf quality averaged in 2006. Throughout the years that this characteristic has been evaluated, a few varieties from each bentgrass species have performed better than the rest. For creeping bentgrasses maintained at a putting green height of cut, Authority, Declaration,

Tyee, and Shark all performed very well, while Penncross, Providence, Pennlinks, Viper, and Crenshaw did not. At a fairway height, Authority, Benchmark, and Declaration creeping bentgrasses exhibited excellent turf quality, while the poorest rated cultivars were Providence, Viper, Penncross, and Crenshaw.

Velvet bentgrasses have also been evaluated for overall turf quality every year. The cultivars Venus, Greenwich, and Villa were among the highest rated in every putting green test in which they were entered. Although the cultivar SR 7200 fared poorly under a 1/8-inch height of cut, it performed as well as Greenwich and Villa under fairway height conditions. The Velvet bentgrass cultivar Barbella and the experimental selection PST-VE52 Bulk did not rate well for turf quality on fairways.

Turf quality was also evaluated for colonial bentgrass. As mentioned previously, colonial bentgrass performs better at fairway cutting heights and has poor quality under putting green conditions. The experimental selections 04-EBM Comp, BCD Comp, PST-Syn-9BC3, and HCG Comp all received high scores, while Bardot, PST-9IR, SRX 781-21, and PST-Syn-9505 did not rate well under fairway cutting heights.

Dollar Spot

In susceptible turfgrasses, *Sclerotinia homoeocarpa* causes spots of dead turf the size of silver dollars. While potentially one of the more damaging turf diseases on golf courses in New Jersey, dollar spot can be easily controlled with the use of fungicides. Unfortunately, disease control can be expensive because dollar spot occurs so frequently, and resistance of the causal agent to fungicides has become more prevalent. In addition, increased fungicide use is not beneficial to the environment. Breeding for dollar spot resistance in bentgrass is an important objective of the Rutgers turfgrass breeding program. Although velvet and colonial bentgrasses are more resistant to dollar spot than creeping bentgrass, the results from recent trials indicate that disease resistance in creeping bentgrass has significantly improved. The creeping bentgrasses Declaration, Kingpin, Benchmark DSR, PST-020 Bulk, and PST-ORR Bulk all rated well for resistance in the 2003 fairway trial (Table 5). Topping the list of the most resistant varieties to this disease in the 2005 fairway test included the velvet bentgrasses CP3 Comp, Villa, and IS-AC-4, Declaration creeping bentgrass, and

colonial bentgrasses FT1 Comp and SRX 7EE (Table 9). The most susceptible selections included Independence and Crenshaw creeping bentgrasses.

Brown Patch

Among the bentgrass species used for turf, velvet bentgrass is typically the most tolerant to brown patch, while colonial bentgrass is the most susceptible. Brown patch ratings were lowest for Kingpin creeping bentgrass and Greenwich velvet bentgrass in the 2003 fairway trial (Table 5), and Greenwich continued to perform well in the 2004 and 2005 fairway trials (Table 7 and 9). In the 2003 fairway trial, a few colonial bentgrasses such as PST-9IR, SRX 781-21, Heriot, SRX 7EE4, and PST-9NG-Bulk were especially susceptible to the disease. In the 2004 trial (Table 7), Viper creeping bentgrass was most susceptible, while in the 2005 trial (Table 9), Penncross and Putter creeping bentgrass sustained the most damage from this disease.

A major emphasis of the Rutgers breeding program has been to improve resistance to brown patch in colonial bentgrass, with dramatic results. In the 2005 fairway trial (Table 9), FT1 Comp colonial bentgrass, specifically selected for brown patch resistance, was much more tolerant of the disease than the standard cultivars SR 7150, SR 7100, Alister, and Tiger II. In the 2004 fairway trial (Table 7), colonial bentgrass BCD Comp was most resistant to the disease, while SRX 7EE5 was most susceptible.

Copper Spot

In the northeast, copper spot has become increasingly troublesome during late spring and early summer due to the warm, wet conditions typical of that time of the year. *Gloeocercospora sorghi* is a fungus that produces 3- to 4-inch, red-brown patches on the turf. In the 2005 putting green trial (Table 8), colonial bentgrass was more resistant to copper spot than both velvet and creeping bentgrasses. Breeding velvet bentgrass cultivars with resistance to copper spot has been an important objective for the Rutgers breeding program. Selections with improved resistance compared to standard cultivars include CP1 Comp, CP2 Comp, and CP3 comp (Table 8).

Spring Green-Up

Spring green-up was evaluated for the 2003 and 2004 putting green trials (Tables 3 and 6) and the 2003 fairway trial (Table 5). Compared to colonial

and creeping bentgrasses, velvet bentgrass does not green up well in the spring and may even exhibit a reddish color during cold winter months. Several creeping bentgrass entries that evaluated well for spring green-up included Kingpin and Benchmark DSR. SR7200 velvet bentgrass was rated best among all of the velvet bentgrass entries. The lowest rated entries were Crenshaw creeping bentgrass and Barbella velvet bentgrass.

Turf Density

Turfgrass density was measured for the 2003 NTEP putting green and fairway trials in October (Tables 3 and 4). The density measurement quantifies the number of shoots per unit area. Overall, turfgrass density in velvet bentgrass exceeds that of creeping and colonial bentgrass species. In the 2003 trials, Villa and SR 7200 velvet bentgrasses rated best for density, while Shark, MacKenzie, and Authority performed the best of the creeping bentgrasses (Table 3 and 4). As breeding efforts have included a push to increase turf density, as expected, older varieties such as the creeping bentgrasses Penncross, Seaside, and Pennlinks II received the lowest ratings for this trait.

Genetic Color

Genetic color was evaluated in October for the 2003 NTEP putting green and fairways trials (Tables 3 and 4). High ratings are associated with plots that have a dark green color, while lighter green or yellowish plots receive lower ratings. Typically, velvet and colonial bentgrasses have a light green color, while creeping bentgrasses are darker green and, in some cases, exhibit an almost blue-green coloration. In the putting green trial (Table 3), T-1 and LS-44 creeping bentgrasses were darker green compared to Imperial and Penncross, which were the lightest in color. T-1 also rated highly for dark green color in the fairway trial (Table 4), while Seaside creeping bentgrass and Bardot colonial bentgrass scored the lowest.

Wear Tolerance

The ability of a turf stand to handle wear is one of the more important traits in maintaining the long-term quality and playability of the surface. Wear to turfgrass can be applied by driving machinery or

walking on the turf or through cultivation procedures. Wear was simulated on the 2002 and 2003 fairway studies (Table 2 and 5) by using a novel wear simulator (Bonos et al, 2001), which is an engine-driven device with rotating rubber paddles that repeatedly hit the turf. Plots of different cultivars were rated for their ability to remain green and dense under these conditions. HCG Comp colonial bentgrass and Venus velvet bentgrass did well in the 2002 trial, and SRX 7CRCO colonial bentgrass performed the best for wear tolerance in the 2003 trial. In the 2002 trial, plots of Providence and Century creeping bentgrass and PST-Syn-9PIN colonial bentgrass had very little remaining living turf after exposure to harsh wear conditions.

ACKNOWLEDGMENTS

New Jersey Experiment Station Publication No. E-12180-5-07. This work was conducted as part of NJAES Project No. 12132, supported by the Rutgers Center for Turfgrass Science, the New Jersey Agricultural Experiment Station, State and Hatch Act funds, other grants and gifts. Additional support was received from the United States Golf Association-Golf Course Superintendents Association of America Research Fund, New Jersey Turfgrass Association, the New Jersey Turfgrass Foundation and the National Turfgrass Evaluation Program.
