2008 RUTGERS TURFGRASS PROCEEDINGS

of the

**New Jersey Turfgrass Expo
December 9-11, 2008
Trump Taj Mahal
Atlantic City, New Jersey**

The Rutgers Turfgrass Proceedings is published yearly by the Rutgers Center for Turfgrass Science, Rutgers Cooperative Extension, and the New Jersey Agricultural Experiment Station, School of Environmental and Biological Sciences, Rutgers, The State University of New Jersey in cooperation with the New Jersey Turfgrass Association. The purpose of this document is to provide a forum for the dissemination of information and the exchange of ideas and knowledge. The proceedings provide turfgrass managers, research scientists, extension specialists, and industry personnel with opportunities to communicate with co-workers. Through this forum, these professionals also reach a more general audience, which includes the public.

This publication includes lecture notes of papers presented at the 2008 New Jersey Turfgrass Expo. Publication of these lectures provides a readily avail-

able source of information covering a wide range of topics and includes technical and popular presentations of importance to the turfgrass industry.

This proceedings also includes research papers that contain original research findings and reviews of selected subjects in turfgrass science. These papers are presented primarily to facilitate the timely dissemination of original turfgrass research for use by the turfgrass industry.

Special thanks are given to those who have submitted papers for this proceedings, to the New Jersey Turfgrass Association for financial assistance, and to Barbara Fitzgerald, Marlene Karasik, and Ann Diglio for administrative and secretarial support.

PERFORMANCE OF TALL FESCUE CULTIVARS AND SELECTIONS IN NEW JERSEY TURF TRIALS

**Jonathan M. Bokmeyer, Ronald F. Bara, Dirk A. Smith, Melissa M. Wilson,
Stacy A. Bonos, and William A. Meyer¹**

Tall fescue (*Festuca arundinacea* Schreb.) is a cool-season grass native to Europe and parts of Africa (Buckner et al., 1979). Tall fescue was originally planted as a forage grass, and it was not until the release of the first tall fescue cultivars in the 1940s that its utility expanded to low maintenance situations. Although tall fescue thrives in a broad range of environments, due in large part to excellent heat and drought tolerance, these earlier cultivars lacked the overall turf quality needed for use in home lawns.

Tall fescue made its way into the turfgrass market with the release of the cultivar Rebel in 1979 (Funk et al., 1981). Since that time, turf breeders have improved the grass to produce cultivars with a darker color, finer leaf texture, lower growth habit, denser turf canopy, and increased resistance to disease (Watkins and Meyer, 2004). Recent tall fescue releases can now be used effectively for a number of medium-high maintenance turf situations including athletic fields, parks, home lawns, and roughs on some golf courses. The deep root system that tall fescue develops enables it to access soil moisture deep in the soil profile. This species is also widely adaptive to many soil types and does not require as many fertilizer inputs as most other cool-season turfgrasses. Many of the improved tall fescue cultivars are comparable to other cool-season turfgrass species in terms of turf quality at mowing heights of 1.5 inches and higher.

The current challenge facing tall fescue breeders is to improve disease resistance and the overall competitive nature of tall fescue cultivars. In the Rutgers Turfgrass Breeding Program, several research trials have been implemented to address these specific challenges. For example, the incorporation of endophytes into tall fescue cultivars has been a primary goal in recent years. Endophytes are fungi that live

in the leaf sheath and stem tissue of tall fescue plants and produce different alkaloids that have been shown to enhance plant tolerance to insect feeding (Funk et al., 1993). In other studies, inoculation and screening techniques have been implemented to improve tall fescue cultivars and selections for disease resistance as well as increased wear tolerance. To compliment the development of new selection techniques, plant breeders continue to collect germplasm with beneficial genes that can be incorporated into the breeding program.

PROCEDURES

Field Establishment and Maintenance

Four tall fescue trials were established at the Rutgers Plant Biology and Pathology Research and Extension Farm at Adelphia, NJ between 2005 and 2007 (Tables 1, 2, 3, and 4). All tests were established in September by hand sowing 0.88 oz of seed per 3 X 5 ft plot (3.7 lb/1000 ft²). All tests were arranged in a randomized complete block design with three replications, and each plot had a 6-inch unseeded border to limit contamination. Broadleaf weeds were controlled with spring or fall applications of 2,4-D, dicamba (Banvel), and MCPP. Dithiopyr (Dimension) was applied in the spring to control annual grassy weeds. In July metalaxyl (Subdue) was applied to prevent Pythium root disease.

Single applications of fertilizer did not exceed 1.0 lb nitrogen/1000 ft². The amount and timing of nitrogen applied to the turf was varied to encourage disease and other stresses. Field trials were mowed regularly (approximately 2 to 3 times per week) with reel mowers to maintain a 1.5-inch height of cut. The

¹Graduate Assistant, Principle Laboratory Technician, Principle Laboratory Technician, Field Researcher IV, Assistant Professor, and Research Professor, respectively, New Jersey Agricultural Experiment Station, School of Environmental and Biological Sciences, Rutgers, The State University of New Jersey, New Brunswick, NJ 08901-8520.

annual rate of nitrogen applied as well as mowing height for each test is presented in Table 5. Based on soil test results, lime was applied as needed to maintain a pH of 6.0 to 6.5. Irrigation was applied to each test as needed to avoid wilting.

Visual Assessment

All tests were rated throughout the growing season for visual turf quality (i.e., overall appearance, turf color, uniformity, density, mowing quality, reduced rate of vertical growth, leaf texture, and damage due to insects and diseases). Other ratings such as spring green-up, color, wear tolerance, density, and damage due to specific diseases were documented when significant differences were evident. All ratings were based on a 1 to 9 scale, where 9 represented the best turf characteristic. Plots were evaluated by a number of turfgrass specialists to reduce the impact of personal bias for particular characteristics. All data were summarized and subjected to an analysis of variance. Means were separated using Fisher's protected least significant difference (LSD) means separation test.

Inoculation

The 2006 and 2007 tall fescue tests (Tables 3 and 4) were screened for resistance to brown patch following field inoculation with two isolates of *Rhizoctonia solani* Kühn, the casual fungus of this disease. Inoculum was prepared by growing two isolates of *R. solani* on sterilized Kentucky bluegrass (*Poa pratensis* L.) seed following the method described by Bonos et al. (2003). The prepared inoculum was then placed in a drop spreader and applied to the field at a rate of 0.2 g/m² in the month of June. To ensure favorable conditions for disease development, light irrigation was applied to the field immediately after inoculation.

Wear Application

A novel wear machine (Bonos et al., 2001) was used to apply wear uniformly over each turf plot in both tall fescue trials established in 2005 (Tables 1 and 2). The wear was applied to one-half of each turf plot, leaving the unworn half as a control. Wear was applied by passing the machine over each plot in one direction and then returning over each plot in the opposite direction. Wear was applied on 10, 19, and 24 June and 2, 7, and 16 July 2008. A total of 4 passes with the wear machine were applied on each

treatment date except for 2 July 2008 when only 2 passes were applied.

RESULTS AND DISCUSSION

Results of the tall fescue tests are found in Tables 1 through 4. All tests are ranked by overall (multiple-year) turf quality averages. A high quality average is generally indicative of better disease resistance, a darker green color, greater turf density and uniformity, finer leaf texture, lower growth habit, improved mowing quality, and less damage due to insects.

Turf Quality

Each year noticeable improvements in overall turf quality are evident in the latest generation of released cultivars of tall fescue. Advancements in color, leaf texture, and density by turf breeders have made tall fescue a suitable choice for most cool-season turfgrass situations. Cultivars such as 3rd Millennium, Falcon V, Shenandoah Elite, Shenandoah III, Cochise IV, and Faith performed consistently well in multiple trials. As tall fescue turf quality continually improves, turfgrass managers are encouraged to continually study all available data so that the best cultivars can be selected for each turf situation.

Disease Resistance

Brown patch is a significant problem for tall fescue turfs in warm, humid environments. As yet, there are no turf-type tall fescue cultivars with complete resistance to this disease. When environmental conditions favoring disease development are present, some damage will be sustained by all available cultivars. This point is illustrated in the brown patch data recorded in Tables 3 and 4; while significant differences existed between cultivars and selections, each plot was affected by the disease to some degree. Cultivars such as Shenandoah III, Shenandoah Elite, and Faith displayed moderate to excellent resistance to brown patch in multiple trials.

Wear Tolerance

One characteristic that limits the use of tall fescue turf in situations such as athletic fields is its slow recovery after traffic stress occurs. Identifying experimental selections and cultivars of tall fescue that are able to recover quickly from damage caused by wear would have a great impact on the utility of tall fescue. The wear tolerance of entries subject to

a total of 22 passes of a wear simulator is presented in Tables 1 and 2. Cultivars that performed best in both trials were Shenandoah III, Shenandoah Elite, and 3rd Millennium.

Other Turf Characteristics

Characteristics that should not be overlooked when selecting cultivars include spring green-up, enhanced genetic color, and density. In 2008 trials, cultivars with the ability to quickly break dormancy and green up in the spring were Faith, Shenandoah III, Van Gogh, and Falcon IV (Table 3). Tall fescue cultivars with enhanced genetic color are suitable choices for mixtures with Kentucky bluegrass; Tombstone, Hunter, and Cochise IV were rated as having the darkest color (Table 3). Finally, cultivars that maintained a high rating for density in multiple trials were Shenandoah Elite and 3rd Millennium (Tables 1 and 2). Although Falcon NG and Shenandoah III also rated well for density, these entries were not evaluated in both trials.

SUMMARY

As plant breeders continue to develop cultivars with improved turf quality and disease resistance, tall fescue is certain to be used more widely in the turf industry. Due to improvements in disease resistance, density, leaf texture, and color, tall fescue has become a more popular selection for many turfgrass situations. These improvements have also made it possible for tall fescue to be used effectively in mixtures with other turfgrass species, especially Kentucky bluegrass. Tall fescue performs better than most other cool-season turfgrasses under high temperature and low moisture conditions and requires fewer inputs. Endophyte-infected tall fescue cultivars are useful in certain stress situations and will continue to be studied. The major weakness of tall fescue is its susceptibility to brown patch, thus the Rutgers breeding program is focusing on developing cultivars that can better handle brown patch disease pressure.
